termite bait system

nemesis | a PCT product

PCT
PEST CONTROL TECHNOLOGIES
INTERNATIONAL PTY LTD

nemesis™ has been designed as a professional termite control product, providing a safe, non-invasive answer to your concerns about termite attack and damage in your home. Every day, countless Australian homes are targeted by these insects, causing thousands of dollars damage to timber structures and fittings. All too often, there is no evidence of their presence until it's too late! We have developed this state-of-the-art system to give you peace of mind when it comes to protecting your valuable asset- your home. We are carrying out ongoing research both in our own right and in partnership with leading institutions to further develop and improve the Nemesis System.

**nemesis—
I've found termites— what now?**

If you discover termites or their mud trails or timber damage, don't panic! (don't disturb them if possible, don't spray them with fly spray- it has no effect on the entire colony). Call a professional pest manager at the earliest opportunity to arrange for a thorough property inspection and advice on treatment options.

- Termite management requires training in locating and detecting activity and colony workings. The pest manager has extensive knowledge of termite biology and behaviour.
- A pest manager is experienced in one of the most important aspects of termite management- property inspection. He is able to correctly interpret inspection results and thus recommend appropriate treatment methods.
- A pest manager understands building construction techniques and how they relate to the planning and implementation of a successful termite management program.
- Termite management professionals are skilled in the servicing and maintenance of the specialised systems that are available for termite control. In particular, those who have undertaken the Nemesis accreditation course are able to fully show you how the Nemesis System can detect colonies and eliminate them from your home.
- The Nemesis System can only be installed by a professional pest manager. PCT fully supports those professionals who have completed the Nemesis Accreditation Course and who install the system in accordance with the Nemesis manual.

**nemesis—
Why choose our system?**

- The NEMESIS System is designed as a second generation system based on input from leading institutions and pest management professionals.
- The in-ground stations feature a very low profile, camouflaged design, ensuring discreet placement and reduced likelihood of damage.
- The timber inserts offer a major advance in baiting technology by way of mimicking real termite grooves and channeling and by ensuring ultra-low disturbance to feeding termites during station inspections and while introducing the Nemesis Bait Matrix to the station.
- The Nemesis baiting stations (both in-ground and above-ground) feature a significant internal volume which enables a maximum bait quantity to be taken by the termite colony in the shortest possible time. This enables a more rapid colony elimination, giving you peace of mind.
- The NEMESIS System is suitable for incorporating with or supplementing traditional chemical barrier systems.
- Termite monitoring and baiting are approved methods of termite colony elimination as per Australian Standard AS3669.3-2000.
- The NEMESIS System is a wholly Australian owned and manufactured system.

**nemesis—
how does the system work?**

Inside your home...

The Nemesis Bait Matrix is particularly attractive to termites—they will feed on it in preference to the timber of your home. This means that if active termites are located within your home, baiting can commence immediately, using specially designed above-ground feeding stations which are strategically placed over the termite workings. The workers will rapidly accept the bait, taking it back to the nest and sharing it with the queen, soldiers & other workers. The termites cannot sense that the bait is affecting their ability to grow and develop. The active ingredient, Chlofloxuron, is not only a proven insect growth regulator, it also keeps the colony being able to reproduce effectively or successfully. The colony consequently loses whole generations of replacement members, it progressively declines and inevitably collapses. The effects of the Nemesis bait are visible and can be tracked. This means that the colony elimination can be reliably determined. The termites' natural habits, food preferences and feeding behaviour are all used to its advantage.

Around your home...

Nemesis in-ground stations are at the forefront of the System—affording your home ongoing protection from termite attack. These stations are placed strategically around the exterior of your home, either in soil, through concrete or under pavers where they become your first line of defence against possible termite attack. In fact, they can be placed at any area of risk on your property! Regular monitoring of these stations at 8 to 12 week intervals, by a pest manager, allows for early detection of foraging termites. When activity is detected in these stations, Nemesis bait is introduced into the upper void of the station, where it is readily taken by the termites. It acts upon the colony in the same manner as for inside your home. Active stations are regularly inspected, at approximately 3 week intervals, and the bait is replenished or reinstalled as required in order to facilitate continuing bait uptake by the termites. When the colony has been eliminated, the residual bait is removed, new timber inserts installed and regular inspections maintained thereafter.

Installation under pavers.

Installation through concrete.

Low profile: 18 reduces tripping hazard and likelihood of damage caused by lawnmowers. Sit at soil level, minimising station visibility. A special tool is required to penetrate station, eliminating tampering by children or pets.

The station features a significant volume of internal space for bait matrix placement ensuring there is an ample quantity present to eliminate a termite colony rapidly. The tightly sealing lid and airtight openings at the upper side of the station reduce the likelihood of regular air exchange.

Again specially designed termite-attractive timber inserts are provided from freshly-milled *Eucalyptus delegatensis* / *E. nigricornis* eucalyptus base of the station. Here, the station has large openings to ensure maximum opportunity for foraging termites to locate the station. The channels and grooves machined into the inserts mimic real termite galleries, further enhancing the baiting opportunity.

TERMITE FACTS:

Termites are small soft bodied insects, commonly referred to as white ants. Although they look a little like ants, they are not ants! There are hundreds of species of termites in Australia. Some are important nest-builders and decayed timber, others feed on grasses, while only a few species cause economic damage to timber.

These economically significant species of subterranean termites travel through soil as they constantly forage for and excavate the site and quality of potential food resources. They seek out cellulose, the primary component of wood. They feed on fibre or cellulose and benefit by excreting it, leaving behind a substance known as chitin. Unfortunately, termites also find cellulose in timber. It leaves a yellow stain, and cause a glistening sheen as a result. They have the potential to be present in a building for several years with few visible signs of activity. Termites form large nests or colonies, with each individual member performing a specific taskwork necessary to ensure the survival and flourishing.

There are several castes within the colony, with clearly defined workloads and responsibilities: **REPRODUCTIVES** (Queen, King & Alate) Every year which conditions are favourable (warm, humid weather), thousands of winged males are released from mature colonies— they fly out and are attracted by light sources. A small number survive, mate as King and Queen and perpetuate the species in a new colony in some cases, the Queen can live for more than 25 years and produce over 500 eggs daily.

WORKERS: The majority of termites are workers. Often in colour they build and maintain the nest, stand for food and distribute it with the colony and the young and act as bury workers. They make these two most essential roles and cause the damage to timber.

SOLDIERS: Relatively few in number, they are responsible for the protection of their colonies against colony members from predators. With characteristic fighting equipment, they will often sacrifice themselves to protect the colony.

GIRO surveys estimate that the risk of termite attack and damage is high. The statistical risk is that one in three houses will be attacked at some stage during their economic life. Bear in mind that most home insurance policies do not cover termite damage.
